

Application of linked list:

Addition of 2 polynomials :-

(1)

linked lists are widely used to represent and manipulate polynomials. Polynomials are the expressions containing no. of terms with non zero coefficients and exponents.

Consider the following polynomial

$$p(x) = a_n x_n^{e_n} + a_{n-1} x_{n-1}^{e_{n-1}} + \dots + a_1 x_1^{e_1} + a_0$$

where a_i are non zero coeffs.

e_i are exponents.

Polynomial Node

```
struct polynode
{
```

```
    int coeff;
```

```
    int expo;
```

```
    struct polynode * link;
```

```
};
```

Addition of 2 polynomials:

Steps involved in adding 2 polynomials are :-

- 1) Read the no. of terms in first polynomial.
- 2) Read the coeff & exponents of the first polynomial.
- 3) Read the no. of terms in the second polynomial.
- 4) Read the coeffs & exponents of the second polynomial.

(5) Set the temporary pointers pl & ql to traverse the 2 polynomials respectively.

a) If both exponents are equal then add the coefficients & store it in the resultant-linked list.

b) If the exponent of the current term in the first polynomial p is less than the exponent of the current term of the second polynomial, it is added to the resultant-linked list. Move the pointer ql to point to the next node in the second polynomial q .

c) If the exponent of the current term in the first polynomial p is greater than the exponent of the current term of the first polynomial q , then the current term of the first polynomial is added to the resultant-linked list. Move the pointer pl to the next node.

(d) Append the remaining nodes of either of the polynomials to the resultant-linked list.

Example

$$p = 3x^2 + 2x + 7$$

$$q = 5x^3 + 2x^2 + x$$

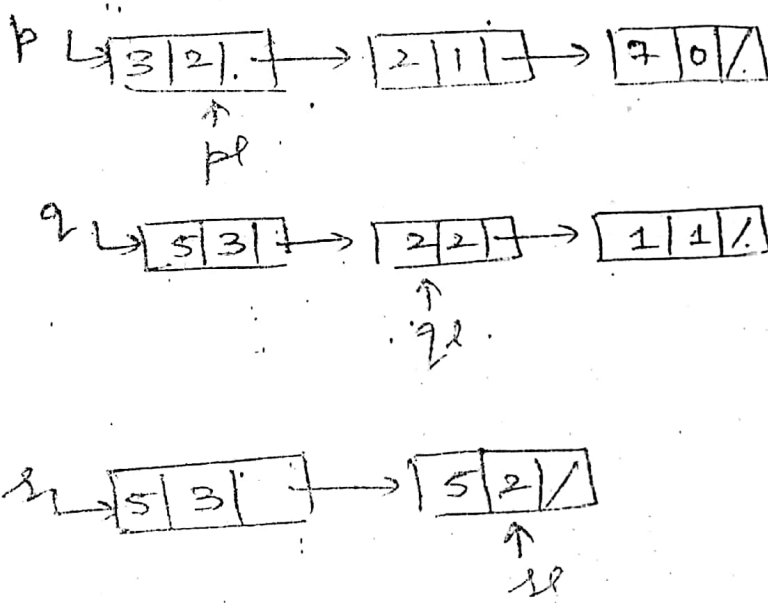

Step 1:

$$\text{expo}(pl) < \text{expo}(ql)$$

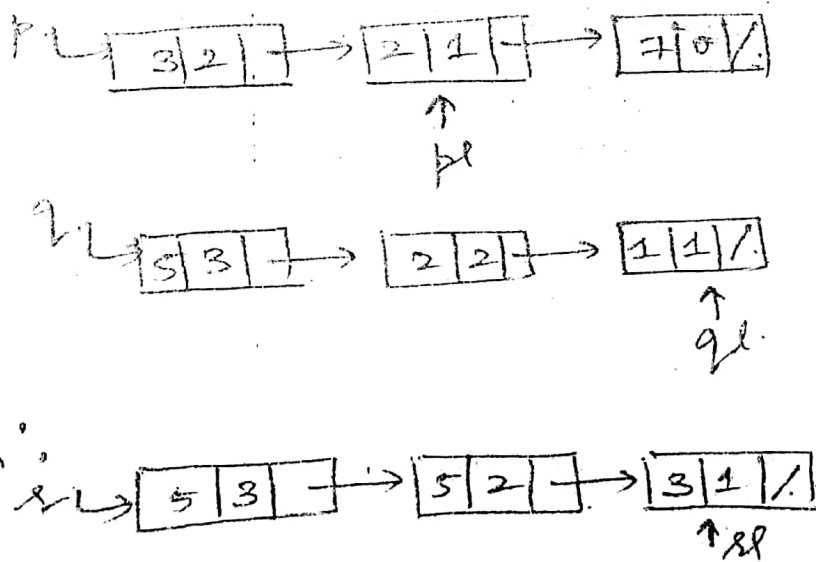

Step 2:

$$\text{expo}(pl) = \text{expo}(ql)$$

Step 3:

$$\text{expo}(pl) = \text{expo}(ql)$$

Step 4:

Step 5:

∴ final solⁿ is

$$P + Q = 5x^3 + 8x^2 + 4x + 7$$
